(Received 25 May 2017)

We report our systematic construction of the lattice Hamiltonian model of topological orders on open surfaces, with explicit boundary terms. We do this mainly for the Levin-Wen string-net model. The full Hamiltonian in our approach yields a topologically protected, gapped energy spectrum, with the corresponding wave functions robust under topology-preserving transformations of the lattice of the system. We explicitly present the wavefunctions of the ground states and boundary elementary excitations. The creation and hopping operators of boundary quasi-particles are constructed. It is found that given a bulk topological order, the gapped boundary conditions are classified by Frobenius algebras in its input data. Emergent topological properties of the ground states and boundary excitations are characterized by (bi-) modules over Frobenius algebras.

Matter phases with intrinsic topological orders (ITOs) not only extend our understanding of phases of matter far beyond the Landau-Ginzburg paradigm^[1,2] but also may support robust quantum memories^[3] and topological quantum computation.^[4–7] Most studies of the dynamical theories of 2d ITOs have been unfortunately limited to closed surfaces (except Ref. [8–10] for the Kitaev model on a disk). On the one hand, closed surface materials are hardly realizable in experiments. This situation hinders the realistic applicability of ITOs. On the other hand, a bulk Hamiltonian theory will be incomplete for a system on open surfaces if its boundary conditions are not specified. In this Letter, we report our explicit and systematic construction of a wide class of boundary Hamiltonians for string-net models, to specify the boundary conditions and to be added to the bulk Levin-Wen bulk Hamiltonian.^[11] We present explicit ground-state wavefunctions and construct creation and hopping operators of boundary excitations in our new approach. (We have also systematically constructed the boundary Hamiltonian of the twisted quantum double model^[12] of ITOs, which is to be reported elsewhere.)

We shall make heavy use of the graphic techniques, of which details can be found in the original references.^[11,13] With the graphic rules, a graph equality can be unambiguously turned into usual algebraic equations involving tensors. Our notations follow the conventions in Ref. [13].

Preliminaries: Non-chiral bulk intrinsic topological phases in (2+1)-D can be studied by effective discrete topological quantum field theories, such as the LW model, an exactly solvable Hamiltonian model defined on 2d spatial trivalent graphs. The LW model is essentially a discrete gauge theory, defined using a uni-

tary fusion category (UFC) \mathcal{C} , e.g. the collection of all representations of a finite or quantum group, as input data (see, e.g., Ref. [14]). For simplicity, we assume that \mathcal{C} is multiplicity free. The Hamiltonian is defined in terms of the $6j$ -symbols over \mathcal{C} . The topological properties of the LW model, such as the ground state degeneracy (GSD) and the topological quantum numbers of the quasi-particle excitations, are ensured by their invariance under the change of Γ by the Pachner moves. There are three elementary Pachner moves, associated with which are respectively three unitary linear maps^[13] in the ground-state subspace:

$$\begin{aligned}
 T_{2 \rightarrow 2} \left| \begin{array}{c} j_1 \quad j_4 \\ j_2 \quad j_3 \\ j_5 \end{array} \right\rangle &= \sum_{j_5} G_{j_3 j_4 j_5}^{j_1 j_2 j_5} v_{j_5} v_{j_5'} \left| \begin{array}{c} j_1 \quad j_4 \\ j_2 \quad j_3 \\ j_5' \end{array} \right\rangle, \\
 T_{1 \rightarrow 3} \left| \begin{array}{c} j_1 \quad j_3 \\ j_2 \end{array} \right\rangle &= \sum_{j_4, j_5, j_6} \frac{v_{j_5} v_{j_6} v_{j_4}}{\sqrt{D}} G_{j_5 j_6 j_4}^{j_1 j_2 j_3} \left| \begin{array}{c} j_1 \quad j_6 \\ j_4 \quad j_3 \\ j_5 \end{array} \right\rangle, \\
 T_{3 \rightarrow 1} \left| \begin{array}{c} j_1 \quad j_6 \\ j_4 \quad j_3 \\ j_2 \end{array} \right\rangle &= \frac{v_{j_5} v_{j_4} v_{j_6}}{\sqrt{D}} G_{j_5 j_4 j_6}^{j_1 j_3 j_2} \left| \begin{array}{c} j_1 \quad j_3 \\ j_2 \end{array} \right\rangle,
 \end{aligned} \tag{1}$$

where j_i 's are inequivalent simple objects (usually called string types) of \mathcal{C} , G 's are the symmetric $6j$ -symbols^[13] over \mathcal{C} with normalization $v_j = 1/G_{00j}^{j*j0}$, and $D = \sum_j v_j^4$. These operators yield a unique transformation between the Hilbert spaces before and after the Pachner moves. We shall denote the unique transformation by \mathcal{T} , which is independent of the path of Pachner moves involved.

Frobenius algebra and boundary Hamiltonian: We propose to use the Frobenius algebras in a UFC to specify boundary conditions and construct boundary terms to be added to the LW Hamiltonian. Let G be

**Corresponding author. Email: yswu@fudan.edu.cn

a symmetric $6j$ -symbol over the string-type set L , the set of all (inequivalent) simple objects of \mathcal{C} . A Frobenius algebra A (in \mathcal{C}) is a subset L_A of L equipped with a multiplication f_{abc^*} , satisfying

$$\begin{aligned} & \text{(associativity)} \sum_c f_{abc^*} f_{cde^*} G_{de^*g}^{abc^*} v_c v_g = f_{age^*} f_{bdg}, \\ & \text{(non-degeneracy)} f_{bb^*0} \neq 0, \quad \forall b \in L_A, \end{aligned} \quad (2)$$

where all indices take values in L_A . Due to the symmetry conditions of the symmetric $6j$ -symbols,^[13] the multiplication has the following defining properties:

$$\begin{aligned} & \text{(unit)} f_{bb^*0} = f_{b0b^*} = f_{0bb^*} = 1, \\ & \text{(cyclic)} f_{abc} = f_{cab}, \\ & \text{(strong)} \sum_{ab} f_{abc} f_{c^*b^*a^*} v_a v_b = d_A v_c, \end{aligned} \quad (3)$$

where $d_A = \sum_{a \in L_A} d_a$ with $d_a = v_a^2$ is the quantum dimension of A .

We can express the associative and strong conditions in a compact way graphically:

$$\mathcal{T} \left(\left| \begin{array}{c} a \quad e \\ \bullet \quad \bullet \\ b \quad d \end{array} \right. \right) = \left| \begin{array}{c} a \quad e \\ \bullet \quad \bullet \\ b \quad d \end{array} \right. \rangle, \quad (4)$$

$$\mathcal{T} \left(\frac{\sqrt{D}}{d_A} \left| \begin{array}{c} \uparrow c \\ \bullet \\ \downarrow c \end{array} \right. \right) = \left| \begin{array}{c} \uparrow c \\ \bullet \\ \downarrow c \end{array} \right. \rangle. \quad (5)$$

Here each vertex carries a multiplication, and an unlabeled thick line implies a summation over its label in L_A . We take this convention in graphical equations throughout this letter.

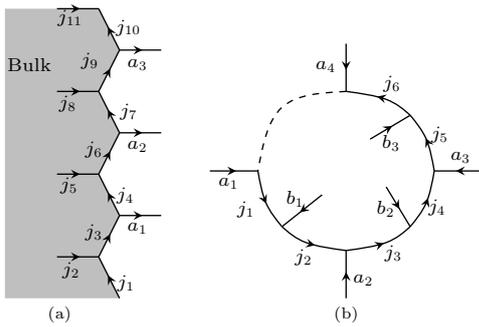

Fig. 1. (a) Boundary is a wall carrying open edges a 's. Bulk edges are the j 's. The bulk edges are not open edges, and they appear so because we neglected the rest of the bulk. (b) When no quasiparticle exists in bulk, a cylindrical system can be effectively described by a circular wall with all bulk plaquettes eliminated by Pachner moves.

For simplicity, let us consider a system on an open surface, outside of which is the vacuum. To each boundary (component) A , we associate a Frobenius algebra L_A , and attach an open edge (or a tail), labeled by a string-type $a \in L_A$, from the vacuum side to each boundary edge. See Fig. 1(a), in which the grey

region represents the bulk of the graph, including the edges along the rim of the grey region. Throughout this letter, we shall adopt this convention.

Similar to transformations (1), we can use the Frobenius algebra A to define unitary transformations associated with 1D Pachner moves on the boundaries of a graph (with $u_a = \sqrt{v_a}$):

$$\begin{aligned} & T_{1 \rightarrow 2} \left| \begin{array}{c} j \\ \uparrow \\ i \end{array} \right. \left. \begin{array}{c} \rightarrow \\ a_1 \end{array} \right. \rangle \\ &= \sum_{a_2, a_3} \frac{u_{a_1} u_{a_2} u_{a_3}}{\sqrt{d_A}} \sum_k v_k f_{a_2^* a_3^* a_1} G_{a_2^* a_3^* k}^{j^* i a_1^*} \left| \begin{array}{c} j \\ \uparrow \\ k \\ \rightarrow \\ a_3 \\ \rightarrow \\ a_2 \\ \uparrow \\ i \end{array} \right. \rangle, \\ & T_{2 \rightarrow 1} \left| \begin{array}{c} j \\ \uparrow \\ k \\ \rightarrow \\ a_3 \\ \rightarrow \\ a_2 \\ \uparrow \\ i \end{array} \right. \rangle \\ &= \sum_{a_1} \frac{u_{a_1} u_{a_2} u_{a_3}}{\sqrt{d_A}} v_k f_{a_2 a_3 a_1} G_{a_2^* k^* a_3}^{j a_1 i^*} \left| \begin{array}{c} j \\ \uparrow \\ i \end{array} \right. \left. \begin{array}{c} \rightarrow \\ a_1 \end{array} \right. \rangle. \end{aligned} \quad (6)$$

where $u_a = \sqrt{v_a}$ (sign of square root may be arbitrarily chosen but if fixed once then for all).

With the boundaries, the topological feature of the entire model is described as follows. The ground-state Hilbert space is invariant under any transformation composed of $T_{2 \rightarrow 2}, T_{1 \rightarrow 3}, T_{3 \rightarrow 1}$ in the bulk and $T_{1 \rightarrow 2}, T_{2 \rightarrow 1}$ on the boundary. Associativity ensures that a product of such transformations is unique. We shall show the uniqueness for boundary Pachner moves $T_{1 \rightarrow 2}, T_{2 \rightarrow 1}$, as that for bulk Pachner moves shown in Ref. [13].

Without loss of generality, consider the transformation from N_1 open edges to N_2 open edges (see Fig. 2). The composition of $T_{1 \rightarrow 2}$ and $T_{2 \rightarrow 1}$ amounts a graph structure with N_1 input edges and N_2 output edges, where each trivalent vertex is attached with a multiplication. From the associativity condition, the transformation presented by the graph in the dashed box is unique.

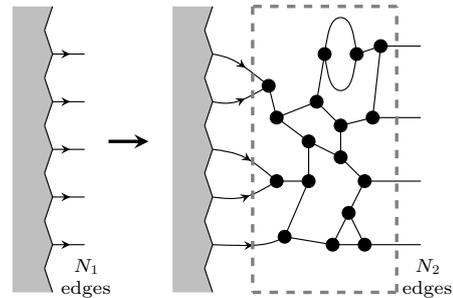

Fig. 2. Sketch of proving the uniqueness of the transformation associated with boundary Pachner moves.

In ground states, the boundary degrees of freedom

are restricted to L_A . The boundary Hamiltonian reads

$$H_{\text{bdry}} = - \sum_n \bar{Q}_n - \sum_p \bar{B}_p, \quad \bar{B}_p = \frac{1}{d_A} \sum_{t \in L_A} v_t \bar{B}_p^t. \quad (7)$$

Here \bar{Q}_n is a boundary edge operator acting on open edge n , which projects the boundary d.o.f. to $L_A \subseteq L$:

$$\bar{Q}_n \left| \begin{array}{c} j_2 \\ \leftarrow a_n \\ j_1 \end{array} \right\rangle = \delta_{a_n \in L_A} \left| \begin{array}{c} j_2 \\ \leftarrow a_n \\ j_1 \end{array} \right\rangle. \quad (8)$$

And \bar{B}_p^t acts on a boundary open plaquette between a pair of nearest neighboring open edges:

$$\bar{B}_p^t \left| \begin{array}{c} j_4 \\ \leftarrow a_2 \\ j_3 \\ \leftarrow a_1 \\ j_2 \\ \leftarrow a_1 \\ j_1 \end{array} \right\rangle = \sum_{a'_1 a'_2 j'_2 j'_3} f_{t^* a'_2^* a_2} f_{a_1 t a'_1^*} u_{a_1} u_{a_2} u_{a'_1} u_{a'_2} \times \\ v_{j_2} v_{j_3} v_{j'_2} v_{j'_3} G_{t^* a'_2^* j'_3}^{j_4 j_3 a_2^*} G_{t^* j'_3^* j_2}^{j_5 j_2 j_3^*} G_{j_1 a_1^* a'_1}^{t^* j_2^* j_2} \left| \begin{array}{c} j_4 \\ \leftarrow a'_2 \\ j'_3 \\ \leftarrow a'_1 \\ j'_2 \\ \leftarrow a'_1 \\ j_1 \end{array} \right\rangle. \quad (9)$$

Following the same convention as in Eq. (2), We can write \bar{B}_p in a more compact fashion as

$$\bar{B}_p \left| \begin{array}{c} j_4 \\ \leftarrow a_2 \\ j_3 \\ \leftarrow a_1 \\ j_2 \\ \leftarrow a_1 \\ j_1 \end{array} \right\rangle = \mathcal{T} \sum_{t a'_1 a'_2} \frac{u_{a'_1} u_{a'_2}}{d_A u_{a_1} u_{a_2}} \left| \begin{array}{c} j_4 \\ \leftarrow a'_2 \\ j_3 \\ \leftarrow a'_1 \\ j_2 \\ \leftarrow a'_1 \\ j_1 \end{array} \right\rangle. \quad (10)$$

The marked (\times) plaquette will be annihilated by the boundary Pachner moves to generate the coefficients in Eq. (9).

Boundary terms \bar{Q}_v and \bar{B}_p are shown to be projections commuting with bulk terms $Q_{v'}$, $B_{p'}$ and other boundary terms $\bar{Q}_{v''}$, $\bar{B}_{p''}$. Correspondence properties between bulk and boundary operators are summarized in Table 1.

Table 1. Correspondence between bulk and boundary operators.

Bulk	Boundary
$B_{p=\Delta} = T_{1 \rightarrow 3} T_{3 \rightarrow 1}$	$\bar{B}_p = T_{1 \rightarrow 2} \cdot T_{2 \rightarrow 1}$
$B_p = \frac{1}{D} \sum_s d_s B_p^s$	$\bar{B}_p = \frac{1}{d_A} \sum_a v_a \bar{B}_p^a$
$B_p^r B_p^s = \sum_t \delta_{rst} B_p^t$	$\bar{B}_p^a \bar{B}_p^b = \sum_c \delta_{abc} \bar{B}_p^c$

Ground states: A (right) module over Frobenius algebra A is a tensor $\rho_{j_1 j_2}^a$, with $a \in L_A$ and $j_1, j_2 \in L$, satisfying

$$T_{2 \rightarrow 2} \left| \begin{array}{c} j_2 \\ \leftarrow a_2 \\ \rho \\ \leftarrow a_1 \\ \rho \\ \leftarrow a_1 \\ j_1 \end{array} \right\rangle = \left| \begin{array}{c} j_2 \\ \leftarrow a_2 \\ \rho \\ \leftarrow a_1 \\ j_1 \end{array} \right\rangle. \quad (11)$$

Here a box ρ at a vertex means that the tensor ρ is associated with the vertex (e.g., $\rho_{j_1 j_2}^c$ on the right-hand side, with a summation over c). We denote all modules over A by Mod_A .

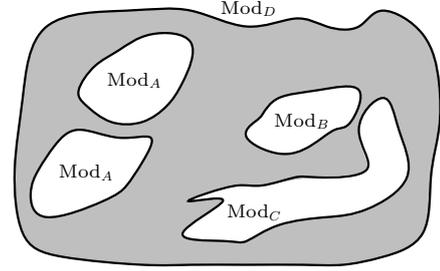

Fig. 3. A surface with multiple disconnected boundaries. An A -boundary has a Mod_A ground state basis.

The local ground states on a boundary component A is characterized by Mod_A . See Fig. 3. The basis (for $M \in \text{Mod}_A$) is given by

$$|\Phi_M\rangle = \left| \begin{array}{c} \rho_M \\ \leftarrow \rho_M \\ \rho_M \\ \leftarrow \rho_M \\ \rho_M \end{array} \right\rangle. \quad (12)$$

Nevertheless, Φ_M may not belong to a ground state of the entire system. The global constraint for no quasiparticle in the bulk may mix local basis on different boundary components. In the following, without loss of generality, we consider the cases on a disk and a cylinder, respectively, with no quasiparticles in the bulk.

On a disk, we can apply the \mathcal{T} transformation to shrink the bulk graph to a single plaquette, bounded by a circle with outward open edges, as in the following equation. The ground state is non-degenerate and expressed by

$$|\Phi\rangle = \sum_M d_M |\Phi_M\rangle, \quad (13)$$

$$\Phi_M \left(\begin{array}{c} a_3 \\ \leftarrow l_3 \\ \rho \\ \leftarrow a_2 \\ \rho \\ \leftarrow a_1 \\ \rho \\ \leftarrow l_1 \\ a_1 \end{array} \right) = u_{a_1} u_{a_2} \cdots [\rho_M]_{l_1 l_2}^{a_1} [\rho_M]_{l_2 l_3}^{a_2} \cdots \quad (14)$$

A cylinder with A - and B -boundaries can be effectively studied on a circular wall (see Fig. 1(b)). The ground states may be degenerate. The ground state degeneracy (GSD) in terms of f and G is explicitly

computed by

$$\begin{aligned}
 \text{GSD} &= \frac{1}{d_A^2} \sum_{st} v_s v_t \sum_{ii'jj'} d_i d_j d_{i'} d_{j'} \\
 &\times \sum_{aa'bb'} v_a v_b v_{a'} v_{b'} f_{s^* a' a} f_{a' s a^*} g_{t^* b' b} g_{b' t b^*} \\
 &\times G_{t^* b' j'}^{j^* i b^*} G_{j' b^* i'}^{i^* a^* j} G_{b^* i^* t}^{j' b i'^*} G_{j' i'^* i}^{s^* a' a} G_{b^* j^* j}^{s^* i i'^*} G_{j^* s^* a'^*}^{a i j^*}.
 \end{aligned} \tag{15}$$

The global constraint on the Mod_A and Mod_B basis leads to a (slightly generalized) (A, B) -bimodule structure P satisfying

$$\mathcal{T} \left(\left| \left(\begin{array}{c} \text{---} \text{---} \\ \text{---} \text{---} \\ \text{---} \text{---} \\ \text{---} \text{---} \end{array} \right) \right\rangle \right) = \left| \begin{array}{c} \text{---} \text{---} \\ \text{---} \text{---} \\ \text{---} \text{---} \\ \text{---} \text{---} \end{array} \right\rangle \tag{16}$$

for $j_1, j_2 \in L$, $a \in L_A$, and $b, c \in L_B$. Note that a box P is not a 4-valent vertex but a composition of two trivalent vertices (in general, two trivalent vertices may carry extra indices). We denote the collection of all (AB) -bimodules by $\text{Mod}_{A|B}$. GSD equals the total number of (A, B) -bimodules. The ground state basis is similarly expressed as in Eq. (14), with ρ replaced by P .

Boundary excitations: The elementary boundary excitations are characterized by topological quasiparticles. On an A -boundary component, quasiparticle species are identified with the (A, A) -bimodules. We construct a creation operator W_M to create a pair of quasiparticles:

$$W_M \left| \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \\ \text{---} \\ \text{---} \end{array} \right\rangle = \mathcal{T} \left(\frac{1}{d_A} \left| \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \\ \text{---} \\ \text{---} \end{array} \right\rangle \right) \tag{17}$$

for $M \in \text{Mod}_{A|A}$. In this example, the operator W_M creates an M -type and M^* -type quasiparticles on both neighboring open edges of the middle open edge. By acting creation operators on ground states, we get an elementary boundary excitation basis $W_M|\Phi\rangle$.

Quasiparticles can move along the boundary under the hopping operator H_M defined by

$$H_M \left| \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right\rangle = \mathcal{T} \left(\left| \begin{array}{c} \text{---} \\ \text{---} \\ \text{---} \end{array} \right\rangle \right), \tag{18}$$

which hops an M -type quasiparticle initially at the bottom open edge upward across the edge.

An example: Consider the input data for Fibonacci model has Label set $L = \{0, 2\}$, sometimes denoted by

$\{1, \tau\}$. Let $\phi = \frac{1+\sqrt{5}}{2}$ be the golden ratio. The quantum dimensions are $d_0 = 1$ and $d_2 = \phi$. The fusion rules are $\delta_{000} = \delta_{022} = \delta_{222} = 1, \delta_{002} = 0$, and the nonzero independent $6j$ -symbols G are given by

$$\begin{aligned}
 G_{000}^{000} &= 1, \quad G_{022}^{022} = G_{222}^{022} = 1/\phi, \\
 G_{222}^{000} &= 1/\sqrt{\phi}, \quad G_{222}^{222} = -1/\phi^2.
 \end{aligned} \tag{19}$$

There are two Frobenius algebras: $A_1 = 0$, or $A_2 = 0 \oplus 2$. Each $j \in L$ is an A_1 -module, with action $[\rho_j]_{jj}^0 = 1$. For A_2 , $L_A = \{0, 2\}$, and $f_{222} = \phi^{-3/4}$. The Frobenius algebra A_2 has two modules: (1) M_0 is A_2 itself, with $[\rho_{M_0}]_{jk}^a = f_{ak^*j}$; (2) $M_1 = 2$, with $[\rho_{M_1}]_{22}^2 = -\phi^{1/4}$. The two Frobenius algebras A_1 and A_2 give rise to equivalent boundary conditions. They both lead to two boundary quasiparticles species and $\text{GSD} = 2$ on cylinder.

Discussion: Here we first elaborate on our motivations. Gapping conditions and GSD of Abelian ITOs on open surfaces have recently been understood.^[15–24] For non-Abelian ITOs on open surfaces, the gapping conditions and GSD counting have recently been solved by the mechanism of anyon condensation^[25,26] and by solving certain algebraic equations.^[27] These studies of ITOs on open surfaces are however algebraic and non-dynamical, which limits their applicability, because they lack a Hamiltonian with explicit boundary terms.

On the other hand, the ground states of an ITO can be effectively described by a continuum Chern-Simons gauge theory. A Chern-Simons theory on an open surface must contain a boundary term,^[28] otherwise the bulk Chern-Simons action is not gauge invariant in the presence of spatial boundary. This fact is usually interpreted as the holographic correspondence between the bulk and the boundary. Such holography exists generally in ITOs in two spatial dimensions. Dynamical theories of topological orders are nevertheless usually formulated using discrete Hamiltonian models. It is thus desirable to demonstrate how the holographic principle works in discrete dynamical models for 2d ITOs.

Our approach has the following advantages over the existing approaches to gapped ITOs on open surfaces. First, our approach depends on the input data of the model, respecting the usual Hamiltonian dynamics. Second, our boundary Hamiltonians, together with the input data, automatically classify the gapped boundaries and domain walls of ITOs. Third, by solving the total Hamiltonian, we can obtain the explicit wave functions of the ground and excited states, all in the form of tensor network states. This will provide us a very detailed dynamic understanding of the stationary topological states of the whole bounded system, especially about what is happening on and near the boundary. For example, our model will enable us to study the boundary excitations explicitly. Also anyon condensation will be understood at more mi-

crossoscopic scales. These studies will be reported later separately. Moreover, certain Abelian^[29] and non-Abelian ITOs^[30,31] on the torus have recently been experimentally simulated on physical systems by imposing periodic boundary conditions. Our approach would make experimental simulation of ITOs on open surfaces possible, and may help construct new quantum computing codes using the boundary states.

Note added: In preparation of this letter, we noticed a very recent work^[32] by Wang, Wen and Witten that constructed the gapped interfaces between symmetry protected topological and symmetry enriched topological states for finite groups.

We appreciate Zhenghan Wang, Liang Kong, Ren Pankovich, Zhu-Xi Luo, and Ethan Lake for discussions.
